

Tutorial 2

Continuous Validation (CV) / Continuous Documentation (CDoc)

Automated Software Engineering
Departamento de Engenharia Informática

In this class, you will create or adapt your CI pipeline to perform Continuous Validation and Continuous Documentation on **GitHub Actions**.

This exercise will give you hands-on experience with:

- Performing a source code analysis automatically.
- Executing unit test through the CI pipeline.
- Generating automatic documentation through the CI pipeline.

1. Configure GitHub Actions

- Such as the previous tutorial, you will need to add `.yaml` files to configure the pipeline. If you are using a different repository, create a directory `.github/workflows/`
- Inside it, add the file `ci.yaml` (the files are available at UCStudent).
- Commit and push these files.

2. Verify the Pipeline

- The files will probably not work well. They have been created for python source code. Adjust them according to the programming language that you are using.

3. Configure the docker-based pipeline

- Add the file `ci-docker.yaml` (also available at UCStudent) to your repository.
- Add the file `Dockerfile` (also available at UCStudent) to your repository. This file should be added to the main source folder.
- Commit and push these files.
- Analyze the build and adjust it properly,
